

FLAT ROTATIONAL SURFACES WITH POINTWISE 1-TYPE GAUSS MAP IN \mathbb{E}^4

FERDAG KAHRAMAN AKSOYAK* AND YUSUF YAYLI

Abstract. In this paper we study general rotational surfaces in the 4-dimensional Euclidean space \mathbb{E}^4 and give a characterization of flat general rotational surface with pointwise 1-type Gauss map. Also, we show that a flat general rotational surface with pointwise 1-type Gauss map is a Lie group if and only if it is a Clifford torus.

1. Introduction

A submanifold M of a Euclidean space \mathbb{E}^m is said to be of finite type if its position vector x can be expressed as a finite sum of eigenvectors of the Laplacian Δ of M , that is, $x = x_0 + x_1 + \dots + x_k$, where x_0 is a constant map, x_1, \dots, x_k are non-constant maps such that $\Delta x_i = \lambda_i x_i$, $\lambda_i \in \mathbb{R}$, $i = 1, 2, \dots, k$. If $\lambda_1, \lambda_2, \dots, \lambda_k$ are all different, then M is said to be of k -type. This definition was similarly extended to differentiable maps, in particular, to Gauss maps of submanifolds [6].

If a submanifold M of a Euclidean space or pseudo-Euclidean space has 1-type Gauss map G , then G satisfies $\Delta G = \lambda(G + C)$ for some $\lambda \in \mathbb{R}$ and some constant vector C . Chen and Piccinni made a general study on compact submanifolds of Euclidean spaces with finite type Gauss map and they proved that a compact hypersurface M of \mathbb{E}^{n+1} has 1-type Gauss map if and only if M is a hypersphere in \mathbb{E}^{n+1} [6].

However the Laplacian of the Gauss map of some typical well known surfaces such as a helicoid, a catenoid and a right cone in Euclidean 3-space \mathbb{E}^3 take a somewhat different form, namely,

$$(1) \quad \Delta G = f(G + C)$$

for some non-zero smooth function f on M and some constant vector C . A submanifold M of a Euclidean space \mathbb{E}^m is said to have pointwise 1-type Gauss map if its Gauss map satisfies (1) for some non-zero smooth function f on M and some constant vector C . A submanifold with pointwise 1-type Gauss map is said to be of the first kind if the vector C in (1) is zero vector. Otherwise, the pointwise 1-type Gauss map is said to be of the second kind.

Surfaces in Euclidean space and in pseudo-Euclidean space with pointwise 1-type Gauss map were recently studied in [7], [8], [10], [11], [12], [13], [14]. Also Dursun and Turgay in [9] gave all general rotational surfaces in \mathbb{E}^4 with proper pointwise 1-type Gauss map of the first kind and classified minimal rotational surfaces with proper pointwise 1-type Gauss map of the second kind. Arslan et al. in [2] investigated rotational embedded surfaces with pointwise 1-type Gauss map. Arslan et al. in [3] gave necessary and sufficient conditions for a Vranceanu rotational surface to have pointwise 1-type Gauss map. Yoon in [19] showed that flat Vranceanu rotational surface with pointwise 1-type Gauss map is a Clifford torus.

In this paper, we study general rotational surfaces in the 4-dimensional Euclidean space \mathbb{E}^4 and give a characterization of flat general rotational surface with pointwise 1-type Gauss map. Also, we show that a flat general rotational surface with pointwise 1-type Gauss map is a Lie group if and only if it is a Clifford torus.

2. Preliminaries

Let M be an oriented n -dimensional submanifold in m -dimensional Euclidean space \mathbb{E}^m . Let $e_1, \dots, e_n, e_{n+1}, \dots, e_m$ be an oriented local orthonormal frame in \mathbb{E}^m such that e_1, \dots, e_n are tangent to M and e_{n+1}, \dots, e_m normal to M . We use the following convention on the ranges of indices: $1 \leq i, j, k, \dots \leq n$, $n+1 \leq r, s, t, \dots \leq m$, $1 \leq A, B, C, \dots \leq m$.

Let $\tilde{\nabla}$ be the Levi-Civita connection of \mathbb{E}^m and ∇ the induced connection on M . Let ω_A be the dual-1 form of e_A defined by $\omega_A(e_B) = \delta_{AB}$. Also, the connection forms ω_{AB} are defined by

$$de_A = \sum_B \omega_{AB} e_B, \quad \omega_{AB} + \omega_{BA} = 0.$$

Then we have

$$(2) \quad \tilde{\nabla}_{e_k}^{e_i} = \sum_{j=1}^n \omega_{ij}(e_k) e_j + \sum_{r=n+1}^m h_{ik}^r e_r$$

and

$$(3) \quad \tilde{\nabla}_{e_k}^{e_s} = -A_r(e_k) + \sum_{r=n+1}^m \omega_{sr}(e_k) e_r, \quad D_{e_k}^{e_s} = \sum_{r=n+1}^m \omega_{sr}(e_k) e_r,$$

where D is the normal connection, h_{ik}^r the coefficients of the second fundamental form h and A_r the Weingarten map in the direction e_r .

For any real function f on M the Laplacian of f is defined by

$$(4) \quad \Delta f = - \sum_i \left(\tilde{\nabla}_{e_i} \tilde{\nabla}_{e_i} f - \tilde{\nabla}_{\nabla_{e_i}^{e_i}} f \right).$$

If we define a covariant differentiation $\bar{\nabla}h$ of the second fundamental form h on the direct sum of the tangent bundle and the normal bundle $TM \oplus T^\perp M$ of M by

$$(\bar{\nabla}_X h)(Y, Z) = D_X h(Y, Z) - h(\nabla_X Y, Z) - h(Y, \nabla_X Z)$$

for any vector fields X, Y and Z tangent to M . Then we have the Codazzi equation

$$(5) \quad (\bar{\nabla}_X h)(Y, Z) = (\bar{\nabla}_Y h)(X, Z)$$

and the Gauss equation is given by

$$(6) \quad \langle R(X, Y)Z, W \rangle = \langle h(X, W), h(Y, Z) \rangle - \langle h(X, Z), h(Y, W) \rangle,$$

where the vectors X, Y, Z and W are tangent to M and R is the curvature tensor associated with ∇ and the curvature tensor R is defined by

$$R(X, Y)Z = \nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z - \nabla_{[X, Y]} Z.$$

Let us now define the Gauss map G of a submanifold M into $G(n, m)$ in $\wedge^n \mathbb{E}^m$, where $G(n, m)$ is the Grassmannian manifold consisting of all oriented n -planes through the origin of \mathbb{E}^m and $\wedge^n \mathbb{E}^m$ is the vector space obtained by the exterior product of n vectors in \mathbb{E}^m . In a natural way, we can identify $\wedge^n \mathbb{E}^m$ with some Euclidean space \mathbb{E}^N where $N = \binom{m}{n}$.

The map $G : M \rightarrow G(n, m) \subset E^N$ defined by $G(p) = (e_1 \wedge \dots \wedge e_n)(p)$ is called the Gauss map of M , that is, a smooth map which carries a point p in M into the oriented n -plane through the origin of \mathbb{E}^m obtained from parallel translation of the tangent space of M at p in \mathbb{E}^m .

Bicomplex number is defined by the basis $\{1, i, j, ij\}$ where i, j, ij satisfy $i^2 = -1, j^2 = -1, ij = ji$. Thus any bicomplex number x can be expressed as $x = x_1 1 + x_2 i + x_3 j + x_4 ij, \forall x_1, x_2, x_3, x_4 \in \mathbb{R}$. We denote the set of bicomplex numbers by C_2 . For any $x = x_1 1 + x_2 i + x_3 j + x_4 ij$ and $y = y_1 1 + y_2 i + y_3 j + y_4 ij$ in C_2 the bicomplex number addition is defined by

$$x + y = (x_1 + y_1) + (x_2 + y_2) i + (x_3 + y_3) j + (x_4 + y_4) ij.$$

The multiplication of a bicomplex number $x = x_1 1 + x_2 i + x_3 j + x_4 ij$ by a real scalar λ is given by

$$\lambda x = \lambda x_1 1 + \lambda x_2 i + \lambda x_3 j + \lambda x_4 ij.$$

With this addition and scalar multiplication, C_2 is a real vector space.

Bicomplex number product, denoted by \cdot , over the set of bicomplex numbers C_2 is given by

$$x \cdot y = (x_1 y_1 - x_2 y_2 - x_3 y_3 + x_4 y_4) + (x_1 y_2 + x_2 y_1 - x_3 y_4 - x_4 y_3) i \\ + (x_1 y_3 + x_3 y_1 - x_2 y_4 - x_4 y_2) j + (x_1 y_4 + x_4 y_1 + x_2 y_3 + x_3 y_2) ij.$$

Vector space C_2 together with the bicomplex product \cdot is a real algebra. Since the bicomplex algebra is associative, it can be considered in terms of matrices. Consider a set of matrices is given by

$$Q = \left\{ \left(\begin{array}{cccc} x_1 & -x_2 & -x_3 & x_4 \\ x_2 & x_1 & -x_4 & -x_3 \\ x_3 & -x_4 & x_1 & -x_2 \\ x_4 & x_3 & x_2 & x_1 \end{array} \right); \quad x_i \in \mathbb{R}, \quad 1 \leq i \leq 4 \right\}.$$

The set Q together with matrix addition and scalar matrix multiplication is a real vector space. Furthermore, this vector space together with matrix product is a real algebra.

The transformation

$$g : C_2 \rightarrow Q$$

given by

$$g(x = x_1 1 + x_2 i + x_3 j + x_4 ij) = \begin{pmatrix} x_1 & -x_2 & -x_3 & x_4 \\ x_2 & x_1 & -x_4 & -x_3 \\ x_3 & -x_4 & x_1 & -x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix}$$

is one to one and onto. Moreover $\forall x, y \in C_2$ and $\lambda \in \mathbb{R}$, we have

$$g(x + y) = g(x) + g(y), \\ g(\lambda x) = \lambda g(x), \\ g(xy) = g(x) g(y).$$

Thus the algebras C_2 and Q are isomorphic [15].

Let $x \in C_2$. Then x can be expressed as $x = (x_1 + x_2i) + (x_3 + x_4i)j$. In this case, there are three different conjugations for bicomplex numbers as follows:

$$\begin{aligned} x^{t_1} &= [(x_1 + x_2i) + (x_3 + x_4i)j]^{t_1} = (x_1 - x_2i) + (x_3 - x_4i)j, \\ x^{t_2} &= [(x_1 + x_2i) + (x_3 + x_4i)j]^{t_2} = (x_1 + x_2i) - (x_3 + x_4i)j, \\ x^{t_3} &= [(x_1 + x_2i) + (x_3 + x_4i)j]^{t_3} = (x_1 - x_2i) - (x_3 - x_4i)j. \end{aligned}$$

3. Flat Rotational Surfaces with Pointwise 1-Type Gauss Map in E^4

In this section, we consider the flat rotational surfaces with pointwise 1-type Gauss map in Euclidean 4- space. Let consider the equation of the general rotation surface given in [16].

$$\varphi(t, s) = \begin{pmatrix} \cos mt & -\sin mt & 0 & 0 \\ \sin mt & \cos mt & 0 & 0 \\ 0 & 0 & \cos nt & -\sin nt \\ 0 & 0 & \sin nt & \cos nt \end{pmatrix} \begin{pmatrix} \alpha_1(s) \\ \alpha_2(s) \\ \alpha_3(s) \\ \alpha_4(s) \end{pmatrix},$$

where $\alpha(s) = (\alpha_1(s), \alpha_2(s), \alpha_3(s), \alpha_4(s))$ is a regular smooth curve in \mathbb{E}^4 on an open interval I in \mathbb{R} and m, n are some real numbers which are the rates of the rotation in fixed planes of the rotation. If we choose the meridian curve α as $\alpha(s) = (x(s), 0, y(s), 0)$ is unit speed curve and the rates of the rotation m and n as $m = n = 1$, we obtain the surface as follows:

$$(7) \quad M : X(s, t) = (x(s) \cos t, x(s) \sin t, y(s) \cos t, y(s) \sin t).$$

Let M be a general rotational surface in \mathbb{E}^4 given by (7). We consider the following orthonormal moving frame $\{e_1, e_2, e_3, e_4\}$ on M such that e_1, e_2 are tangent to M and e_3, e_4 are normal to M :

$$\begin{aligned} e_1 &= \frac{1}{\sqrt{x^2(s) + y^2(s)}} (-x(s) \sin t, x(s) \cos t, -y(s) \sin t, y(s) \cos t), \\ e_2 &= (x'(s) \cos t, x'(s) \sin t, y'(s) \cos t, y'(s) \sin t), \\ e_3 &= (-y'(s) \cos t, -y'(s) \sin t, x'(s) \cos t, x'(s) \sin t), \\ e_4 &= \frac{1}{\sqrt{x^2(s) + y^2(s)}} (-y(s) \sin t, y(s) \cos t, x(s) \sin t, -x(s) \cos t), \end{aligned}$$

where $e_1 = \frac{1}{\sqrt{x^2(s)+y^2(s)}} \frac{\partial}{\partial t}$ and $e_2 = \frac{\partial}{\partial s}$. Then we have the dual 1-forms as:

$$\omega_1 = \sqrt{x^2(s) + y^2(s)} dt \quad \text{and} \quad \omega_2 = ds.$$

By a direct computation we have components of the second fundamental form and the connection forms as:

$$h_{11}^3 = b(s), \quad h_{12}^3 = 0, \quad h_{22}^3 = c(s),$$

$$h_{11}^4 = 0, \quad h_{12}^4 = -b(s), \quad h_{22}^4 = 0,$$

$$\omega_{12} = -a(s)\omega_1, \quad \omega_{13} = b(s)\omega_1, \quad \omega_{14} = -b(s)\omega_2,$$

$$\omega_{23} = c(s)\omega_2, \quad \omega_{24} = -b(s)\omega_1, \quad \omega_{34} = -a(s)\omega_1.$$

By covariant differentiation with respect to e_1 and e_2 , a straightforward calculation gives:

$$(8) \quad \begin{aligned} \tilde{\nabla}_{e_1} e_1 &= -a(s)e_2 + b(s)e_3, \\ \tilde{\nabla}_{e_2} e_1 &= -b(s)e_4, \\ \tilde{\nabla}_{e_1} e_2 &= a(s)e_1 - b(s)e_4, \\ \tilde{\nabla}_{e_2} e_2 &= c(s)e_3, \\ \tilde{\nabla}_{e_1} e_3 &= -b(s)e_1 - a(s)e_4, \\ \tilde{\nabla}_{e_2} e_3 &= -c(s)e_2, \\ \tilde{\nabla}_{e_1} e_4 &= b(s)e_2 + a(s)e_3, \\ \tilde{\nabla}_{e_2} e_4 &= b(s)e_1, \end{aligned}$$

where

$$(9) \quad a(s) = \frac{x(s)x'(s) + y(s)y'(s)}{x^2(s) + y^2(s)},$$

$$(10) \quad b(s) = \frac{x(s)y'(s) - x'(s)y(s)}{x^2(s) + y^2(s)},$$

$$(11) \quad c(s) = x'(s)y''(s) - x''(s)y'(s).$$

The Gaussian curvature is obtained by

$$(12) \quad K = \det(h_{ij}^3) + \det(h_{ij}^4) = b(s)c(s) - b^2(s).$$

If the surface M is flat, from (12) we get

$$(13) \quad b(s)c(s) - b^2(s) = 0.$$

Furthermore, by using (5), (6) we obtain the equations of Gauss and Codazzi as follows:

$$(14) \quad a'(s) + a^2(s) = b^2(s) - b(s)c(s)$$

and

$$(15) \quad b'(s) = -2a(s)b(s) + a(s)c(s),$$

respectively.

By using (4), (8) and straight-forward computation, the Laplacian ΔG of the Gauss map G can be expressed as

$$(16) \quad \begin{aligned} \Delta G &= (3b^2(s) + c^2(s)) (e_1 \wedge e_2) + (2a(s)b(s) - a(s)c(s) - c'(s)) (e_1 \wedge e_3) \\ &+ (-3a(s)b(s) - b'(s)) (e_2 \wedge e_4) + (2b^2(s) - 2b(s)c(s)) (e_3 \wedge e_4). \end{aligned}$$

Remark 3.1. *Similar computations to above computations are given for tensor product surfaces in [4].*

Now we investigate the flat rotation surface with the pointwise 1-type Gauss map. From (13), we obtain that $b(s) = 0$ or $b(s) = c(s)$. We assume that $b(s) \neq c(s)$. Then $b(s)$ is equal to zero and (15) implies that $a(s)c(s) = 0$. Since $b(s) \neq c(s)$, it implies that $c(s)$ is not equal to zero. Then we obtain as $a(s) = 0$. In that case, by using (9) and (10) we obtain that $\alpha(s) = (x(s), 0, y(s), 0)$ is a constant vector. This is a contradiction. Therefore $b(s) = c(s)$ for all s . From (14), we get

$$(17) \quad a'(s) + a^2(s) = 0$$

whose trivial solution and non-trivial solution are given by

$$a(s) = 0$$

and

$$a(s) = \frac{1}{s + c},$$

respectively. We assume that $a(s) = 0$. By (15) $b = b_0$ is a constant, and so is c . In that case by using (9), (10) and (11), x and y satisfy the following differential equations

$$(18) \quad x^2(s) + y^2(s) = \lambda^2 \quad \lambda \text{ is a non-zero constant,}$$

$$(19) \quad x(s)y'(s) - x'(s)y(s) = b_0\lambda^2,$$

$$(20) \quad x'(s)y''(s) - x''(s)y'(s) = b_0.$$

From (18) we may put

$$(21) \quad x(s) = \lambda \cos \theta(s), \quad y(s) = \lambda \sin \theta(s),$$

where $\theta(s)$ is some angle function. Differentiating (21) with respect to s , we have

$$(22) \quad x'(s) = -\theta'(s)y(s) \quad \text{and} \quad y'(s) = \theta'(s)x(s).$$

By substituting (21) and (22) into (19), we get

$$\theta(s) = b_0s + d, \quad d = \text{const.}$$

And since the curve α is a unit speed curve, we have

$$b_0^2\lambda^2 = 1.$$

Then we can write components of the curve α as:

$$x(s) = \lambda \cos(b_0s + d) \quad \text{and} \quad y(s) = \lambda \sin(b_0s + d), \quad b_0^2\lambda^2 = 1.$$

On the other hand, by using (16) we can rewrite the Laplacian of the Gauss map G with $a(s) = 0$ and $b = c = b_0$ as follows:

$$\Delta G = 4b_0^2(e_1 \wedge e_2),$$

that is, the flat surface M is pointwise 1-type Gauss map with the function $f = 4b_0^2$ and $C = 0$, that is, the Gauss map is of usual 1-type. Even if it is a pointwise 1-type Gauss map of the first kind.

Now we assume that $a(s) = \frac{1}{s+c}$. Since $b(s)$ is equal to $c(s)$, from (15) we get

$$b'(s) = -a(s)b(s),$$

or we can write

$$b'(s) = -\frac{b(s)}{s+c},$$

whose the solution is given by

$$b(s) = \mu a(s), \quad \mu \text{ is a constant.}$$

By using (16) we can rewrite the Laplacian of the Gauss map G with $c(s) = b(s) = \mu a(s)$ as:

$$(23) \quad \Delta G = (4\mu^2 a^2(s))(e_1 \wedge e_2) + 2\mu a^2(s)(e_1 \wedge e_3) - 2\mu a^2(s)(e_2 \wedge e_4).$$

We suppose that the flat rotational surface has pointwise 1-type Gauss map. From (1) and (23), we get

$$(24) \quad 4\mu^2 a^2(s) = f + f \langle C, e_1 \wedge e_2 \rangle,$$

$$(25) \quad 2\mu a^2(s) = f \langle C, e_1 \wedge e_3 \rangle,$$

$$(26) \quad -2\mu a^2(s) = f \langle C, e_2 \wedge e_4 \rangle.$$

Then, we have

$$(27) \quad \langle C, e_1 \wedge e_4 \rangle = 0, \quad \langle C, e_2 \wedge e_3 \rangle = 0, \quad \langle C, e_3 \wedge e_4 \rangle = 0.$$

By using (25) and (26) we obtain

$$(28) \quad \langle C, e_1 \wedge e_3 \rangle + \langle C, e_2 \wedge e_4 \rangle = 0.$$

By differentiating the first equation in (27) with respect to e_1 and by using (8), the third equation in (27) and (28), we get

$$(29) \quad 2a(s) \langle C, e_1 \wedge e_3 \rangle + \mu a(s) \langle C, e_1 \wedge e_2 \rangle = 0.$$

Combining (24), (25) and (29) we then have

$$(30) \quad \mu (f - 4(a^2(s) + \mu^2 a^2(s))) = 0.$$

We assume that $\mu \neq 0$. Then

$$(31) \quad f = 4(a^2(s) + \mu^2 a^2(s)),$$

that is, a smooth function f depends only on s . By differentiating f with respect to s and by using the equality $a'(s) = -a^2(s)$, we get

$$(32) \quad f' = -2a(s)f.$$

By differentiating (25) with respect to s and by using (8), (24), the third equation in (27), (31), (32) and the equality $a'(s) = -a^2(s)$, we have

$$\mu a^3 = 0.$$

Since $a(s) \neq 0$, it follows that $\mu = 0$. This is a contradiction. So in equation (30) $\mu = 0$. Then we obtain that $b = c = 0$ and the surface M is a totally geodesic. In that case Gauss map becomes harmonic.

Thus we can give the following theorem and corollary.

Theorem 3.2. *Let M be the flat rotational surface given by the parameterization (7). Then M has pointwise 1-type Gauss map if and only if M is either totally geodesic or it is parameterized by*

$$(33) \quad X(s, t) = \left(\begin{array}{l} \lambda \cos(b_0 s + d) \cos t, \lambda \cos(b_0 s + d) \sin t, \\ \lambda \sin(b_0 s + d) \cos t, \lambda \sin(b_0 s + d) \sin t \end{array} \right), \quad b_0^2 \lambda^2 = 1,$$

where b_0, λ and d are real constants.

Corollary 3.3. *Let M be a non totally geodesic flat rotational surface given by the parameterization (7). If M has pointwise 1-type Gauss map, then the Gauss map G on M is of 1-type.*

Corollary 3.4. *Let M be a non totally geodesic flat rotation surface given by the parameterization (7). If M has pointwise 1-type Gauss map, then the profile curve is a circle.*

Now we give a relationship between rotational surfaces with pointwise 1-type Gauss map and Lie groups. Let the hyperquadric P be given by

$$P = \{x = (x_1, x_2, x_3, x_4) \neq 0; \quad x_1x_4 = x_2x_3\}.$$

We consider P as the set of bicomplex number

$$P = \{x = x_11 + x_2i + x_3j + x_4ij; \quad x_1x_4 = x_2x_3, \quad x \neq 0\}.$$

The components of P are easily obtained by representing bicomplex number multiplication in matrix form.

$$\tilde{P} = \left\{ M_x = \begin{pmatrix} x_1 & -x_2 & -x_3 & x_4 \\ x_2 & x_1 & -x_4 & -x_3 \\ x_3 & -x_4 & x_1 & -x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix}; \quad x_1x_4 = x_2x_3, \quad x \neq 0 \right\}.$$

Theorem 3.5. [15] *The set of P together with the bicomplex number product is a Lie group.*

Proof. \tilde{P} is a differentiable manifold and at the same time a group with group operation given by matrix multiplication. The group function

$$\cdot : \tilde{P} \times \tilde{P} \rightarrow \tilde{P}$$

defined by $(x, y) \rightarrow x \cdot y^{-1}$ is differentiable. So (P, \cdot) can be made a Lie group so that g is a isomorphism. \square

Remark 3.6. *The surface M given by the parameterization (7) is a subset of P*

Remark 3.7. *Let M be a Vranceanu surface. If the surface M is flat, then it is given by*

$$X(s, t) = \left(e^{ks} \cos s \cos t, e^{ks} \cos s \sin t, e^{ks} \sin s \cos t, e^{ks} \sin s \sin t \right),$$

where k is a real constant [19]. In that case we can say that a flat Vranceanu surface together with the bicomplex number product is a Lie subgroup of P . Also, a flat Vranceanu surface with pointwise 1-type Gauss map is a Clifford torus [19] and it is given by

$$X(s, t) = (\cos s \cos t, \cos s \sin t, \sin s \cos t, \sin s \sin t)$$

and Clifford Torus together with the bicomplex number product is a Lie subgroup of P . See for more details [1].

Theorem 3.8. *Let M be a non totally geodesic flat rotation surface with pointwise 1-type Gauss map given by the parameterization (33) with $d = 2k\pi$. Then M is a Lie group with bicomplex number product if and only if it is a Clifford torus.*

Proof. We assume that M given by the parameterization (33) is a Lie group with the group operation of bicomplex number product. Then we have

$$(34) \quad X(s_1, t_1) \cdot X(s_2, t_2) = \lambda X(s_1 + s_2, t_1 + t_2).$$

Since M is a group (34) implies that $\lambda = 1$. Since $b_0^2 \lambda^2 = 1$, it follows that $b_0 = \varepsilon$, where $\varepsilon = \pm 1$. In that case the surface M is given by

$$X(s, t) = (\cos \varepsilon s \cos t, \cos \varepsilon s \sin t, \sin \varepsilon s \cos t \sin \varepsilon s \sin t)$$

and M is a Clifford torus, that is, the product of two plane circles with the same radius. Conversely, Clifford torus is a flat rotational surface with pointwise 1-type Gauss map which can be obtained by the parameterization (33) and it is a Lie group with bicomplex number product. This completes the proof. \square
