**Abstract** We report the results of detailed experimental and theoretical studies on the molecular structure and vibrational spectra of metal(II) halide complexes of 1,3-bis(4-pyridyl)propane  $[M(N_2C_5H_4)_2X_2]$ , where M represents Zn or Hg, and X represents Cl, Br, or I. The FT-infrared spectra (FT-IR) and FT-Raman spectra of the metal complexes of the 1,3-bis(4-pyridyl)propane molecule in the powder form were recorded between the 400–4000 and 5–3500  $\text{cm}^{-1}$  regions, respectively. The molecular geometry and vibrational frequencies of the metal complexes of 1,3-bis(4-pyridyl)propane in the ground state were calculated using density functional theory (B3LYP functional) with LANL2DZ and SDD as basis sets. The total energy distributions (TED) among the symmetry coordinates of the normal modes were computed for the low-energy structure of the molecules. Complete vibrational assignments based on the calculated TED values are given.

## Introduction

Supramolecular chemistry is the study of the chemistry and collective behavior of organized ensembles of molecules—of interactions between, rather than within, molecules. This field has attracted the attention of many research groups. The main challenges encountered in such studies are the strategic construction of specific supramolecular arrangements and comprehension of the relationship between these structures and their physical–chemical properties. 1,3-bis(4-pyridyl)propane (Bpp) is a very flexible versatile bifunctional ligand. The metal–organic coordination polymers of the Bpy [4,4′-pyridine] and Bpp ligands have attracted the continuous attention of researchers in recent years [1]. Two new coordination polymers with the general formula  $[Mn(C_4O_4)(Bpp)_2(H_2O)]$  and  $[Co(C_4O_4)(Bpp)_2(H_2O)]$  where  $C_4O_4 =$  squarate ion] have been synthesized and characterized by vibrational spectroscopy [Raman and infrared (IR)], X-ray diffraction and thermal analysis. These two compounds are isostructural, containing Bpp and the squarate ligand coordinated to the metal sites, as well as two water molecules, in a distorted octahedral geometry. The synthesis, crystal structure, and vibrational spectra of the coordination polymers with Bpp and squarate ion ligands and transition metal ions (M:  $Mn^{+2}$ ,  $Co^{+2}$ ,  $Ni^{+2}$ ,  $Cu^{+2}$ , and  $Zn^{+2}$ ) have been described [2, 3]. All compounds are isostructural, and Bpp is not coordinated to the metal site since it is in cationic form due to the protonation of N atoms from the pyridyl rings. An extensive literature on networks crystallized from different dipyrindyl ligands with various transition metal ions now exists. Networks prepared from flexible dipyrindyl ligands are of interest to many researchers because of the possible occurrence of different ligand conformations within the lattice. The presence of these different conformations means that

different topologies in polymeric structures can be attained using this ligand [4].

1,3-bis(4-pyridyl)propane is an interesting flexible bidentate ligand. The bpp molecule can adopt four discrete conformations [5–7]: *transoid–transoid* (*TT*), *gauche–gauche* (*GG*), *transoid–gauche* (*TG*), and *gauche–gauche'* (*GG'*) depending on the different N-to-N distances or dihedral angles. The Bpp ligand adopts the most stable *TT* conformation with dihedral angles of  $-180^\circ$  ( $C_{20}-C_{17}-C_{14}-C_{11}$ ) and  $180^\circ$  ( $C_{17}-C_{14}-C_{11}-C_3$ ) [8, 9]. These N–N bond distances for these conformations have been determined to be in the range of 9.1–10.1 Å for the *TT* conformation, 8.6–9.2 Å for the *TG* conformation, 3.9–5.3 Å for the *GG* conformation, and 6.7–8.6 Å for *GG'* conformation [10, 11]. Based on these distances, free Bpp can be considered to be most stable in the *TT* conformation in the metal(II) halide complexes of Bpp.

In the study reported here, we investigated the molecular structure and vibrational spectra of the title complexes in their ground states. To the best of our knowledge, the experimental and theoretical spectroscopic properties of the title complexes have not yet been studied in detail. We compared the Fourier transform (FT)–IR and FT-Raman spectra of the title complexes with theoretical vibrational data and also compared the experimental vibrational spectra of the title complexes with those of free Bpp. In a recent investigation, we assigned the vibrational modes of Bpp by means of quantum chemical calculations [8]. Here, the vibrational assignments of the normal modes were made based on the calculated total energy distribution (TED) values.

### Computational details

Quantum chemical calculations were carried out with the Gaussian 03 program package [12], together with Gaussview molecular visualization program [13]. The optimized geometry of the title complexes in the ground state were performed applying DFT (B3LYP) with the LANL2DZ and SDD basis sets. Vibrational spectra were calculated using this theory. The calculated harmonic frequencies were also scaled by corresponding scaling factor (<http://srdata.nist.gov/cccbdb/vsf.asp>). The TED of vibrational modes was calculated by using the scaled quantum mechanics (SQM) program [14].

### Experimental

The Bpp molecule was purchased from the Sigma Aldrich Chemical Company (St. Louis, MO) with a stated purity >98%; it was used as such without further purification.

**Table 1** Analytic data on the prepared complexes

Complexes	Carbon <sup>a</sup>	Nitrogen <sup>a</sup>	Hydrogen <sup>a</sup>
Zn(BPP)Cl <sub>2</sub>	47.14/46.67	8.48/8.37	4.80/4.21
Zn(BPP)Br <sub>2</sub>	37.11/37.13	6.66/6.72	3.32/3.35
Zn(BPP)I <sub>2</sub>	30.17/29.78	5.41/5.11	2.72/2.70

<sup>a</sup> Ratios represent the amount found/amount calculated and are expressed as a percentage

The M(Bpp)X<sub>2</sub> (M: Zn or Hg; X: Cl, Br, or I) complexes were prepared by the following method: metal salts (Cl, Br, or I) were dissolved in absolute ethanol (10 ml) to which 1 mmol of the Bpp solution in ethanol was then added. The mixture was stirred using a magnetic stirrer at room temperature. The precipitated complexes were filtered, washed with ether, and dried. The freshly prepared complexes were analyzed for C, H and N on a LECO-932 model analyzer (LECO Corp, St. Joseph, MI). The results of C, N and H analyses for the complexes are given in Table 1.

The title complexes are in powder forms at room temperature. The FT–IR spectra of the samples were recorded between 400 and 4000 cm<sup>-1</sup> on a Mattson 1000 FT–IR spectrometer (Mattson, Fremont, CA) that was calibrated using polystyrene bands. The samples were prepared as a KBr disc. The FT-Raman spectra of the sample were recorded between the 5 and 3500 cm<sup>-1</sup> region on a Bruker FRA 106/S FT-Raman instrument (Bruker, Billerica, MA) using 1064 nm excitation from an Nd:YAG laser. The detector is a liquid nitrogen-cooled Ge detector.

### Results and discussion

#### Geometrical structures

The optimized bond lengths and bond angles of the title complexes are listed in Electronic Supplementary Material (ESM) Tables S1 and S2. The atom numbering scheme of the title complexes are shown in Fig. 1. Optimized geometric parameters of Zn title complexes and Hg(Bpp)I<sub>2</sub> are compared with corresponding published experimental data [15–17]. However, there is no published experimental data available on the Hg(Bpp)Cl<sub>2</sub> and Hg(Bpp)Br<sub>2</sub> complexes; consequently, we compared our data on these complexes with available data on other Hg(Bpp)I<sub>2</sub> complexes. The theoretical calculations pertain to isolated complexes in gaseous phase although the experimental results belong to complexes in solid phase. As seen in Tables S1 and S2, the experimental values are slightly larger than theoretical

**Fig. 1** Metal complexes of the 1,3-bis(4-pyridyl)propane (Bpp) structure and numbering of the atoms. *M*: Zn or Hg, *X*: Cl, Br, or I

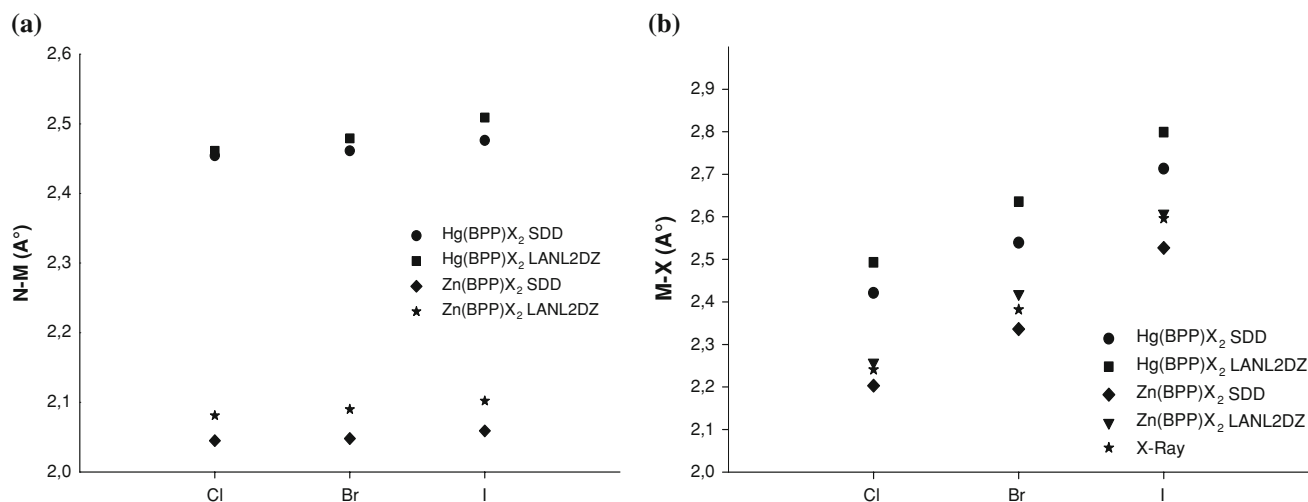

values. In general, however, the calculated values are in good agreement with X-ray data of studied complexes.

The Bpp ligand molecule bridges the Zn(II) or Hg(II) atoms to form a one-dimensional chain complex. This structure; metal(II) atoms (*M*: Zn or Hg) is coordinated by two nitrogen atoms from the pyridine and two halide ligands. The coordinated geometric structure of the metal atom is a distorted tetrahedral, with the asymmetric unit of the title complexes containing half of the formula  $M(\text{Bpp})X_2$  (*M*: Zn or Hg; *X*: Cl, Br, or I). The whole chain is generated by two crystallographic mirror planes: one resides through  $X_{31}-M_{30}-X_{32}$ , and the other resides through  $H_{15}-C_{14}-H_{16}$ ; these were obtained at  $111.75^\circ$  and  $111.50^\circ$  ( $N-Zn-N$ ) for  $Zn(\text{Bpp})Cl_2$  and  $Zn(\text{Bpp})Br_2$ , respectively [15, 16]. The calculated standard deviation of the difference (SDD) values of the corresponding angle was  $107.20^\circ$  and  $105.77^\circ$  for  $Zn(\text{Bpp})Cl_2$ ,  $Zn(\text{Bpp})Br_2$ , respectively.

The Zn–X bond lengths of the title complexes were found to be slightly different: Zn–X bond lengths are

predicted at  $2.203 \text{ \AA}$  (for Cl),  $2.336 \text{ \AA}$  (for Br), and  $2.547 \text{ \AA}$  (I) in the calculations. As seen in Fig. 2a, both the LANL2DZ basis set and X-ray data increase in the same order  $I > Br > Cl$ . The Zn–X bond lengths of the Hg complexes are slightly larger than those of the Zn complexes.

The M–N bond lengths are between  $2.045 \text{ \AA}$  and  $2.509 \text{ \AA}$ . As seen Fig. 2b, the order of the M–N bond lengths are  $Zn(\text{Bpp})Cl_2$  ( $2.081 \text{ \AA}$ )  $<$   $Zn(\text{Bpp})Br_2$  ( $2.090 \text{ \AA}$ )  $<$   $Zn(\text{Bpp})I_2$  ( $2.102 \text{ \AA}$ ) and  $Hg(\text{Bpp})Cl_2$  ( $2.481 \text{ \AA}$ )  $<$   $Hg(\text{Bpp})Br_2$  ( $2.479 \text{ \AA}$ )  $<$   $Hg(\text{Bpp})I_2$  ( $2.509 \text{ \AA}$ ) for the LANL2DZ basis set. The order of the M–N bond lengths are  $Hg(\text{Bpp})Cl_2$  ( $2.454 \text{ \AA}$ )  $>$   $Zn(\text{Bpp})Cl_2$  ( $2.045 \text{ \AA}$ ) and  $Hg(\text{Bpp})Br_2$  ( $2.460 \text{ \AA}$ )  $>$   $Zn(\text{Bpp})Br_2$  ( $2.048 \text{ \AA}$ ) for the SDD basis set. The M–N bond lengths of Zn complexes are about  $0.3 \text{ \AA}$  (SDD) and  $0.45 \text{ \AA}$  (LANL2DZ) shorter than those of the Hg complexes. It is noted that the M–N bond length values depend on the halogen for a given metal complex and that they decrease in the order  $I > Br > Cl$  [18].

**Fig. 2** The N–M (a) and M–X (b) bond lengths of the metal complexes of Bpp. *M*: Zn or Hg, *X*: Cl, Br, or I

## Vibrational assignments

The metal complexes of Bpp consist of 32 atoms with  $C_s$  symmetry. The 90 normal vibrations are distributed as 49  $A'$  (in-plane) + 41  $A''$  (out-of-plane). All of the vibrations are active in both FT-IR and FT-Raman spectra. The calculated frequencies with experimental data of the ligand are presented in Tables 2 and 3. Theoretically computed IR and Raman spectra of  $M(\text{Bpp})X_2$  ( $M$ : Zn or Hg;  $X$ : Cl, Br, or I) are given in Figs. S1 and S2 of the ESM. The FT-IR and FT-Raman spectra of the title complexes are illustrated in Figs. 3 and 4.

Analysis of the hetero-aromatic structure shows the presence of C–H stretching vibrations in the region 3000–3200  $\text{cm}^{-1}$ , which is the characteristic region for the ready identification of C–H stretching vibrations. In this study, the C–H stretching vibrations of the pyridine rings were observed at 3057 (Cl), 3055 (Br) and 3057  $\text{cm}^{-1}$  (I) in the FT-IR spectra of the Zn complexes; this peak was observed at 3051  $\text{cm}^{-1}$  for the free ligand in the FT-IR spectra [8]. The other C–H peak was observed at 3040 (Cl), 3037 (Br), 3034  $\text{cm}^{-1}$  (I) in the FT-IR spectra of the Zn complexes; the corresponding peak was observed at 3029  $\text{cm}^{-1}$  for the free ligand [8]. We observed that these vibrations shifted slightly to higher frequencies in the FT-IR and FT-Raman spectra of the title complexes.

The C–H stretching of the methylene groups are at lower frequencies than those of the aromatic ring. The  $\text{CH}_2$  stretching vibrations of the free Bpp molecule were observed at 2905, 2929, 2944 and 2971  $\text{cm}^{-1}$  in the FT-IR spectra and at 2902, 2927 and 2975  $\text{cm}^{-1}$  in the FT-Raman spectra [8]. The  $\text{CH}_2$  stretching vibrations of the Zn metal complexes were observed at 2933, 2954, 2989  $\text{cm}^{-1}$  (Cl) in the FT-IR spectra of the Zn complexes. The  $\text{CH}_2$  stretching vibrations of Hg complexes were observed at 2930, 2952, and 2983  $\text{cm}^{-1}$  (Cl) in the FT-IR spectra of the Hg complexes. Out-of-plane rocking  $\text{CH}_2$  mode of the free ligand appeared at 831 (IR) and 826  $\text{cm}^{-1}$  (Ra) [8]. This peak was observed at 837 [for  $\text{Hg}(\text{Bpp})\text{Cl}_2$ ] and 838  $\text{cm}^{-1}$  [for  $(\text{Zn}(\text{Bpp})\text{Cl}_2)$ ] in the FT-IR spectra. The theoretically computed value shows an excellent agreement with experimental results.

Asymmetric  $\text{CH}_2$  stretching vibrations were seen to shift slightly towards higher frequencies, whereas symmetric  $\text{CH}_2$  stretching was observed to shift slightly towards lower frequencies in the FT-IR and FT-Raman spectra of metal complexes. The symmetric  $\text{CH}_2$  and asymmetric  $\text{CH}_2$  stretching vibrations of the Zn and Hg complexes are shown in Figs. 5 and 6, respectively.

The spectral region between 1600 and 1650  $\text{cm}^{-1}$ , where ring stretching modes are expected, is very important in the Bpp ligand coordination analysis. The ring stretching band shows up at 1605  $\text{cm}^{-1}$  for the free ligand;

this peak has been observed to shift to higher frequencies (around 1620  $\text{cm}^{-1}$ ) when Bpp is coordinated to the metal ion [1, 5]. In the free ligand molecule, this band was observed at 1605 and 1606  $\text{cm}^{-1}$  in the FT-IR and FT-Raman spectra, respectively [8]. In our study, the peak ring stretching vibrations of the Hg complexes were observed at 1611 (Cl), 1610 (Br), and 1608  $\text{cm}^{-1}$  (I) in the FT-IR spectra; in comparison, these peaks were observed at 1619 (Cl), 1619 (Br), and 1618  $\text{cm}^{-1}$  (I) in the FT-IR spectra of the Zn complexes. The ring stretching vibrations of the Zn complexes are slightly larger than those of the Hg complexes (Fig. 7).

The bands between 220 and 300  $\text{cm}^{-1}$  are assigned to M–N stretching vibration. We expect that the  $\nu(\text{M–N})$  mode will shift to lower frequencies with increasing M–N bond lengths. The  $\nu(\text{M–N})$  mode of the Zn complexes is larger than that of the Hg complexes and, therefore, the M–N bond lengths in the Hg complexes are larger than those of the Zn complexes. This mode was observed experimentally at 249 (for  $\text{Cl}_2$ ), 240 (for  $\text{Br}_2$ ), and 232  $\text{cm}^{-1}$  (for  $\text{I}_2$ ) in the FT-Raman spectra of the Hg complexes. This peak was observed at 238 (for  $\text{Cl}_2$ ), 224 (for  $\text{Br}_2$ ) and 222  $\text{cm}^{-1}$  (for  $\text{I}_2$ ) in the FT-Raman spectra of the Zn complexes. As seen in Fig. 2a and Tables S1 and S2, in the complexes studied, decreases in the calculated M–N bond lengths in the order  $\text{I} > \text{Br} > \text{Cl}$  occurred concurrently with increases in the M–N stretching frequencies.

The total shifts are given at the bottom of Tables 2 and 3. For any given metal, therefore, it should be possible to compare the shift values of the isomorphous complexes as well as observe the effect of changing the stoichiometry of the complex and of changing the counter ligand from Cl, Br, and I. These shift values for isomorphous complexes show a progressive increase across the period from Zn to Hg, and this correlates with increases in the second ionization potential of metals [20, 21]. Similar shifts were observed in the vibrational spectra of pyridine and pyridine derivative halide complexes [19–21] and were explained by the mechanical coupling of pyridine (or pyridine derivative) vibrations with the M–N (pyridine or pyridine derivative) vibrational modes [19, 21, 22]. Therefore, we infer that the M–N (Bpp) bond strength and thus the M–N [1,3-bis(4-pyridyl)propane] stretching mode frequency increase in the same order. It is also noted that for isomorphous complexes the shift values depend on the halogen and that for a given metal, it decreases in the order  $\text{Cl} > \text{Br} > \text{I}$ .

## Conclusion

The molecular structure and vibrational frequencies of the title complexes have been calculated using the

**Fig. 3** The Raman and infrared spectra of Zn(Bpp)X<sub>2</sub>. X: Cl, Br, or I

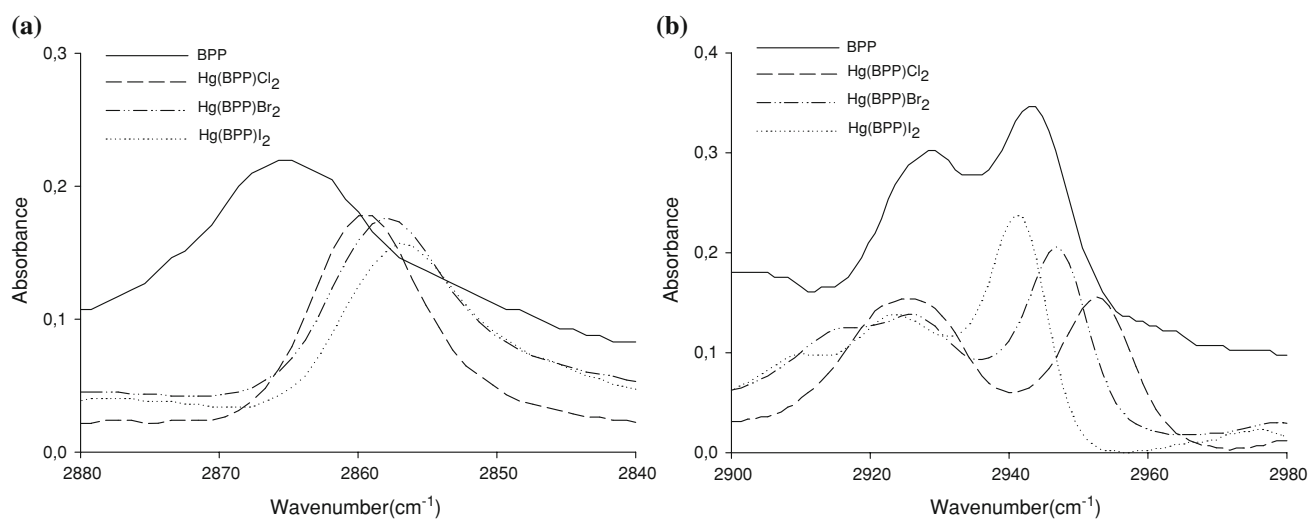

B3LYP functional in conjunction with the LANL2DZ and SDD basis sets approach for molecular vibrational problems. The calculated vibrational wave numbers and optimized geometric parameters were compared with experimentally derived ones. The good agreement between the frequencies calculated by density functional methods and the experimental results indicates provides solid evidence for the reliability of FT-IR and FT-Raman

**Fig. 4** The Raman and infrared spectra of Hg(Bpp)<sub>2</sub>X<sub>2</sub>. X: Cl, Br, and I

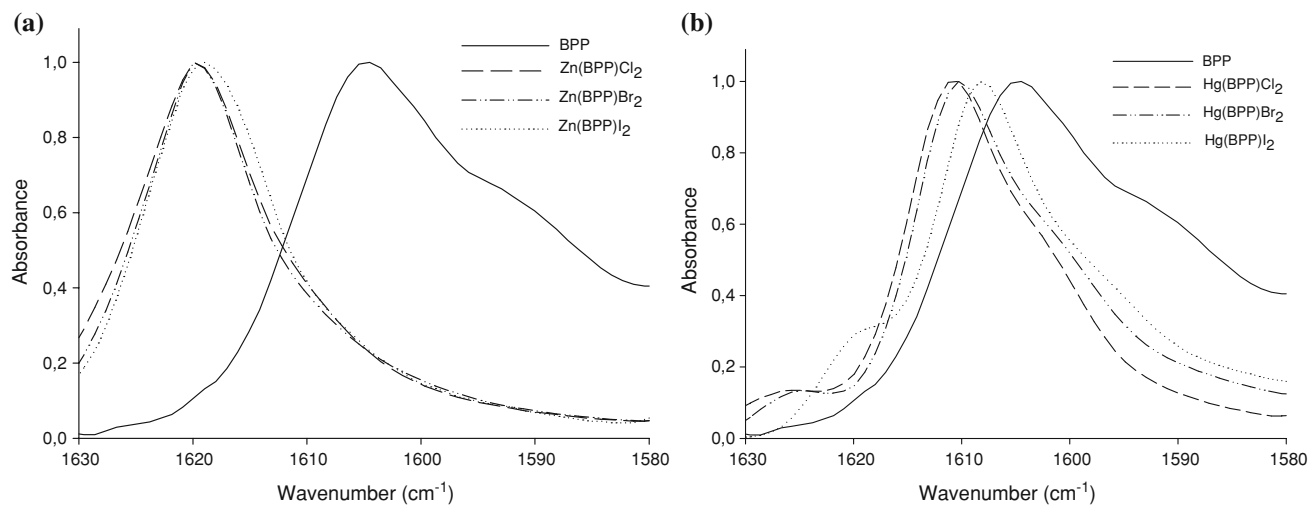

spectra to predict the coordination effects on Bpp vibrations. Asymmetric CH<sub>2</sub> stretching vibrations showed a small shift towards higher frequencies, whereas symmetric CH<sub>2</sub> stretching showed a small shift towards lower frequencies in the FT-IR and FT-Raman spectra of metal complexes. Ring stretching vibrations shifted to higher frequencies when free ligand was coordinated to the metal ion.

**Fig. 5** The symmetric CH<sub>2</sub> (a) and the asymmetric CH<sub>2</sub> (b) stretching vibrations of Zn complexes

**Fig. 6** The symmetric CH<sub>2</sub> (a) and the asymmetric CH<sub>2</sub> (b) stretching vibrations of Hg complexes

**Fig. 7** The ring stretching vibrations of Zn (a) and Hg (b) complexes

**Acknowledgments** This work was supported by the Research Fund of the University of Gazi, project numbers: 30/2005-01. We wish to thank the central laboratory of METU for recording the Raman spectra of the samples and Gazi University, Arts and Science Faculty, Department of Chemistry, for recording the infrared spectra of the samples.
